AutoCAD 2018 was introduced on 7th September 2017. AutoCAD – Basic and Advanced Features An AutoCAD drawing is made up of a collection of objects, called entities, such as lines, circles, text and annotations, that are assigned a particular style, or specification of attributes. Entity styles are in turn assigned various properties (or attributes). The drawing is constructed through manipulation of these entities and properties, starting with a minimal set and building up towards more complex structures. While designing objects, a user may wish to apply certain properties to just a subset of the entities, such as color, text style, dimensions and styles, etc., or to the entire drawing. The options used for doing so are called properties and are defined in a separate property sheet, or property table. These properties may be assigned to an entity, so that they are applicable to the entity itself, or to another entity. The drawing editor allows you to apply them to a given entity, or entity group, at one time. Objects are represented in AutoCAD as editable containers, which are organized in layers or sections. Layers may be categorized as areas, such as floor, walls and ceilings, and cross sections, such as doors, windows, shelves, supports, beams, joists, and the like. Sections may be drawn vertically or horizontally. Every object can have as many layers as needed, and every layer may have as many sections as needed. Layers are sometimes referred to as “sub-objects,” but layers are in fact containers for a collection of objects. Layers are displayed in drawing tools such as selection, dimension, and annotation tools, allowing you to choose which objects are visible when drawing a particular section of the object. Layers are organized in toolbars, and individual properties for objects are stored in tabbed property panels. Layers are visible or hidden when they are selected. In AutoCAD, the user may organize an entire drawing into “scopes,” a concept that allows the user to separate certain parts of the drawing into more manageable, logical, groups. Scopes can be useful for the professional user who uses AutoCAD for most of their projects. In Auto

Q: Check if IQueryable Contains I have an IQueryable Collection that I am performing a search on. I'd like to check whether or not a specific string is contained in the collection before retrieving the elements in the query. Is there a built-in method to do that? For example, given a predicate: IQueryable query = from c in MyCollection where c.SomeField.Contains(myString) select c; Is there a built-in method to check that the SomeField is actually containing myString, or is this best done via separate checks? A: You can use Enumerable.Contains with IEnumerable var query = MyCollection.Where(c => c.SomeField.Contains(myString)); A: The best solution for checking if a string is in the property of a LINQ object is to use LINQ. You can do it like this if(MyCollection.Any(x => x.SomeField.Contains(myString)) { //Do something with your collection } For the string overload there is also a Contains method in String class: if(myString.Contains(MyCollection.Select(x => x.SomeField).ToArray())) { //Do something with your collection } 12 "] That means that each of the three elements of the sequence does in fact contain the correct number of 1s, 2s, and 3s. To verify this, we can
