Over the last few years Docker has become the poster boy for software containers. Adopting a good container solution has become an integral part of modern software development. There are two main reasons why they are so popular. Firstly, they solve one of the major problems plaguing IT: the problem of legacy. By porting all of the software across to containers all of the software is written to be portable. The second reason why software containers are becoming increasingly popular is because it allows the developer to build applications out of smaller, manageable pieces. Docker has made this possible by providing a consistent way of packaging the parts together in such a way that applications can be deployed as an image. Using Crane we can have multiple Docker engines running at the same time. It is also a very extensible container image builder, it can be used to create containers for other Docker engines as well as multiples different Linux distributions. Interface: Crane's interface has changed a lot over the past year and has been reworked into a single window that should be relatively easy to navigate. For this reason, there is now a single main page that stores a small navbar with options that change depending on where in the installation process. The current main page takes you through the following states: – 1 – Create a container – 2 – Create a new project – 3 – Existing project, add dockerfile – 4 – Existing project, edit dockerfile – 5 – Existing project, start project with container – 6 – Existing project, edit Dockerfile – 7 – Existing project, run dockerfile – 8 – Existing project, update config New projects have a tabbed UI that changes with each page. The tabs are: – 1 – Add image – 2 – Repository with source files – 3 – Base image The interface allows users to create, edit, and execute Dockerfiles. Furthermore, the creation of docker container images is also possible. By expanding the container image toolbox, users can easily run, edit, and compile containers, and the toolbox also offers the ability to import containers. The toolbox itself offers three different types of tool: Dockerfile This tool allows users to create and edit their own Dockerfiles, with the help of a set of GUI controls. In addition to the functionality provided by existing tools such as the Dockerfile editor offered by Prime, the utility also provides some new features such as the ability to clone and save existing Dockerfiles, and the ability to add aliases to configure common Dockerfile variables. Prepare Container This tool can be used for preparing images. Its main functionality is

providing users with the ability to link existing docker containers with the current docker daemon. The tool can be used to run containers, and to have the containers run without having to reconfigure the daemon.

Container Image This tool is used for the creation, management, and execution of docker containers. It provides users with the ability to push and pull container images, and to run containers. In addition, users can use the tool to import, update, and convert containers, and to manage users' credentials and passwords. Lastly, the container management and execution tool also provides the ability to create docker volumes, and to shutdown and start container instances.
