Normal neural cell differentiation is characterized by the progressive reduction of cytotoxic potential and by the blockade of apoptotic pathways leading to the elimination of potentially altered or mutated cells. The process of neuronal differentiation, which is closely related to apoptosis, may lead to the development of several neurodegenerative diseases in which apoptosis activation seems to be involved. We have previously observed that during rat cerebellar development, apoptosis is activated at a time when the neurons committed to differentiate are still present, and provides a good model to study the effect of chemicals or injury on the differentiation process. The objective of the present work was to analyze apoptosis induction in NB-2a and PC-12 cells, two cell lines derived from neural cells, and to compare it to apoptosis induction in cerebellar neuronal cells. We have found
