The power switch needs to have a low on-resistance. I have experimented with different types of switches but the current I get from them is quite low. I think the problem is that the IGBTs have large on-resistance which increase the overall resistance of the circuit. It seems there is no good way of choosing the right switch for the job. I have come across this document which talks about a specific type of switch: They talk about a low on-resistance of 0.1 Ω with a maximum voltage of 600 V. So for a typical supply voltage of 12 V this would mean that the load would be able to draw about 9 A. This is very low. For instance, hobby circuits typically draw about 5 A or less. I can't seem to find anything that talks about this specific switch. Can anyone tell me what the name of this particular type of switch is? Edit: I tried searching for it but I can't seem to find it. I have searched for low on-resistance MOSFETs but this query is just returning results that have low on-resistance and not low on-resistance with a specific voltage or current rating. A: As shown on the datasheet, the name of this device is CSD12301. Edit If you want to make a power switch, you might be able to get away with a Darlington pair
