What I have yet to find is a solid example of what the subdocument schema really is and why it is beneficial. I understand that this is a vast topic and I'm not asking for specific answers, but I'd appreciate it if someone could point me towards some resource or article where someone has already solved this particular issue. For example, I have a document with the following properties: { _id: "234567890", VehicleID: "v1" } Then, I have an extra property that I'd like to add to this document as a subdocument: { _id: "234567890", VehicleID: "v1" PanelID: "p1" } Is this type of structure possible/beneficial? Would it be better to have another document that defines each possible PanelID or would I just have a list of PanelIDs? A: Using a document with a wide variety of properties within the same collection is fine. Let's say you wanted to pull out just the PanelID, you would be able to query the document and pull out that value: db.vehicle.findOne({VehicleID: "v1"}, { PanelID:
