with dementia in HIV-1-infected patients. Alzheimer's disease (AD) is the most common form of dementia in older adults. Insulin-degrading enzyme (IDE) is a gene mapped to chromosome 10p which contains a strong candidate locus for AD. Our aim was to investigate whether the apolipoprotein E (APOE) and IDE polymorphisms

are risk factors for Alzheimer's disease in HIV-1-infected patients. We obtained DNA samples from a cohort of 109 HIV-1-infected and 59 HIV-1-uninfected patients. Genomic DNA was amplified in a polymerase chain reaction based restriction fragment length polymorphism analysis for APOE, and amplified by means of a

sequence-specific primer using a single-strand conformation polymorphism technique for the IDE promoter. Our study demonstrates no association of APOE genotypes (epsilon2, epsilon3, epsilon4) with diagnosis of Alzheimer's disease in HIV-1-infected patients. The most prevalent allele for IDE was IDE2.2, which

occurred more frequently in patients infected with HIV-1. The IDE2.2 allele was also associated with the diagnosis of HIV-1 dementia. There was no association of IDE alleles with other neuropsychiatric disorders in HIV-1-infected patients.(JTA) — A school building in Ukraine that was used to house Jews

during World War II was reopened by its Ukrainian Jewish students and Jewish community. The opening ceremony of the Ilyka Ber Mramorny school, or "Little World," at Tel-Aviv University on Saturday was attended by students and faculty, reports The Times of Israel. The school, built in 1939, was dedicated in 1954 as a Jewish school.

The school closed in 1945, when the Soviet Union occupied Ukraine. Its reopening was the result of a collaboration between the Jewish community and Russian billionaire Mikhail Fridman, whose parents were Holocaust survivors, c6a93da74d
